EXPLICIT EXPONENTIAL RUNGE–KUTTA METHODS FOR SEMILINEAR PARABOLIC PROBLEMS[*]

MARLIS HOCHBRUCK[†] AND ALEXANDER OSTERMANN[‡]

Abstract. The aim of this paper is to analyze explicit exponential Runge–Kutta methods for the time integration of semilinear parabolic problems. The analysis is performed in an abstract Banach space framework of sectorial operators and locally Lipschitz continuous nonlinearities. We commence by giving a new and short derivation of the classical (nonstiff) order conditions for exponential Runge–Kutta methods, but the main interest of our paper lies in the stiff case. By expanding the errors of the numerical method in terms of the solution, we derive new order conditions that form the basis of our error bounds for parabolic problems. We show convergence for methods up to order four, and we analyze methods that were recently presented in the literature. These methods have classical order four, but they do not satisfy some of the new conditions. Therefore, an order reduction is expected. We present numerical experiments which show that this order reduction in fact arises in practical examples. Based on our new conditions, we finally construct methods that do not suffer from order reduction.

Key words. exponential integrators, Runge–Kutta methods, semilinear parabolic problems, stiff order conditions, explicit high-order methods, convergence, order reduction

1. Introduction. Motivated by recent interest in exponential integrators for stiff problems [3, 9, 11, 12] and inspired by the promising numerical experiments reported in those papers, we present error bounds for a class of explicit exponential Runge–Kutta methods for semilinear parabolic problems

$$(1.1) \qquad u'(t) + Au(t) = g(t, u(t)), \qquad u(t_0) = u_0.$$

The idea behind exponential integrators is an old one and dates back to the 1960s. The early literature on exponential one-step methods comprises [4, 6, 14, 23, 24, 25]. In most of those papers, the methods were constructed by making use of the variation-of-constants formula for the solution of (1.1). All of them use the exponential function of the matrix $-hA$ in order to step from time t to time $t+h$, or some rational approximations thereof. Exponential multistep methods have been considered in [13, 21, 26].

Although the first exponential integrators were proposed many years ago, such methods have not been regarded as practical for a long time. This view, however, has changed recently as new methods for computing or approximating the product of a matrix exponential function with a vector have been developed; see the review [19] and references therein. For large problems, polynomial approximations have to be applied, in general, either based on Chebyshev polynomials or using variants of the Lanczos process or the Arnoldi method. (These techniques are also reviewed in [19].) For parabolic problems it has been shown recently that one can achieve grid independent convergence of the Lanczos process by working with a shifted and inverted matrix

[5, 20]. The linear systems arising in each step of the Lanczos process can either be solved directly (if fast direct solvers are available) or with a preconditioned iterative method. Details can be found in [5].

The numerical comparisons presented in [11, 12, 18] reveal a number of examples where explicit exponential integrators outperform standard integrators. However, while the convergence behavior of implicit or linearly implicit Runge–Kutta or multi-step methods for parabolic problems is nowadays well understood [15, 16], no analysis is known so far for explicit exponential integrators. In our paper [10] we analyzed implicit exponential Runge–Kutta methods. There, a crucial step in the convergence proofs was to show that all stages have a sufficiently small defect when the true solution is inserted in place of the numerical solution. This is no longer true for explicit schemes of order at least three. Therefore, new techniques have to be used for proving error bounds in this case. Our aim with this paper is to derive new order conditions for stiff problems and, based on these, to give error bounds for parabolic problems. The new conditions will then enable us to analyze the methods presented in the literature and, further, to construct new methods that do not suffer from order reduction.

The outline of the paper is as follows. In section 2, we define a general class of exponential Runge–Kutta methods and give conditions under which these methods preserve equilibria. We further give a simple and short derivation of the classical order conditions for arbitrary order. Our convergence analysis of (1.1) will be performed in the standard framework of analytic semigroups and locally Lipschitz continuous nonlinearities in a Banach space. This abstract framework is recalled in section 3. Our main results are contained in section 4, where we derive new order conditions for explicit exponential Runge–Kutta methods applied to parabolic problems. These conditions, which comprise the classical order conditions, are given in Table 2 up to order four. Based on them, we show convergence for explicit exponential Runge–Kutta methods up to order four, under appropriate temporal smoothness of the exact solution. The convergence results for the exponential Euler method and for second-order methods are given in Theorems 4.2 and 4.3, respectively, and our main result is Theorem 4.7. The new order conditions are further used in section 5 to analyze methods from the literature and to construct new methods. In particular, we will show that neither of the exponential classical Runge–Kutta methods from [3, 12] is of order four, in general, when applied to parabolic problems. Our order conditions enable us, however, to construct a new exponential variant of the classical Runge–Kutta method which is of full order four. In section 6 we present numerical experiments which show that the order reductions predicted by our theory may in fact arise in practical examples.

2. Order conditions and general properties. We consider the following general class of one-step methods for solving (1.1):

$$(2.1a) \qquad u_{n+1} = \chi(-hA)u_n + h\sum_{i=1}^{s} b_i(-hA)G_{ni},$$

$$(2.1b) \qquad U_{ni} = \chi_i(-hA)u_n + h\sum_{j=1}^{s} a_{ij}(-hA)G_{nj},$$

$$(2.1c) \qquad G_{nj} = g(t_n + c_j h, U_{nj}).$$

Here, the method coefficients χ, χ_i, a_{ij}, and b_i are constructed from exponential functions, or rational approximations of such functions evaluated at the matrix or operator $-hA$.

For consistency reasons, we always assume that $\chi(0) = \chi_i(0) = 1$. It seems worth mentioning that (2.1) reduces to a Runge–Kutta method with coefficients $b_i = b_i(0)$ and $a_{ij} = a_{ij}(0)$ if we consider the limit $A \to 0$. The latter method will be called the *underlying Runge–Kutta method* henceforth, while (2.1) will be referred to as an *exponential Runge–Kutta method* in the following. We suppose throughout the paper that the underlying Runge–Kutta method satisfies

$$\sum_{j=1}^{s} b_j(0) = 1, \qquad \sum_{j=1}^{s} a_{ij}(0) = c_i, \quad i = 1, \ldots, s,$$

which makes it invariant under the transformation of (1.1) to autonomous form.

A desirable property of numerical methods is that they preserve equilibria $u^\star$ of the autonomous problem $u'(t) + Au(t) = g(u(t))$. Requiring $U_{ni} = u_n = u^\star$ for all i and $n \geq 0$ immediately yields the necessary and sufficient conditions. It turns out that the coefficients of the method have to satisfy

$$(2.2) \qquad \sum_{j=1}^{s} b_j(z) = \frac{\chi(z) - 1}{z}, \qquad \sum_{j=1}^{s} a_{ij}(z) = \frac{\chi_i(z) - 1}{z}, \quad i = 1, \ldots, s.$$

Without further mention, we will assume throughout the paper that these conditions are fulfilled.

With the help of (2.2), the functions χ and χ_i can be eliminated in (2.1). The numerical scheme then takes the form

$$(2.3a) \qquad u_{n+1} = u_n + h \sum_{i=1}^{s} b_i(-hA)\big(G_{ni} - Au_n\big),$$

$$(2.3b) \qquad U_{ni} = u_n + h \sum_{j=1}^{s} a_{ij}(-hA)\big(G_{nj} - Au_n\big).$$

Conditions (2.2) also imply that we can restrict ourselves to autonomous problems

$$(2.4) \qquad u'(t) + Au(t) = g(u(t)), \qquad u(t_0) = u_0,$$

since all methods satisfying (2.2) are invariant under the transformation of (1.1) to autonomous form.

For $A = 0$, the methods reduce to classical Runge–Kutta methods, for which the order conditions are well known. In the case of $A \neq 0$, nonstiff order conditions of order up to 5 have been presented by Friedli [6] using Taylor series expansion of the exact and the numerical solutions; see also [25] and references therein. Our approach below is based on trees, which allows us to extract the order conditions for arbitrary orders in a systematic and simple way, very similar to classical Runge–Kutta methods. A more technical approach based on the theory of B-series is chosen in [1].

Writing (2.4) in the form

$$u' = g(u) - Au = F(u)$$

shows that the Taylor expansion of the exact solution contains the elementary differentials of F which are represented by the usual trees. Note that these differentials coincide with those of g except for $F' = g' - A$ and F itself. Splitting the trees that contain F', we obtain trees with two kinds of nodes. The nodes corresponding to A

are represented by open (white) circles in Table 1, whereas the evaluation of F and of derivatives of g is represented by filled (black) circles. This gives the subclass of bicolored trees with black branching nodes and black leaves.

For the numerical scheme written in the form (2.3), we define $\widetilde{F}(u) = g(u) - Au_n$. Then, (2.3) can be formally interpreted as an ordinary Runge–Kutta method with the usual trees corresponding to the elementary differentials of $\widetilde{F}$. The differentials of $\widetilde{F}$ coincide with those of g except for the evaluation of the functions themselves where $F(u_n) = \widetilde{F}(u_n)$. Moreover, taking the series expansion of the coefficients a_{ij} and b_i into account leads to the same bicolored trees as for the exact solution.

The derivation of the order conditions from the trees proceeds as follows. For sake of simplicity in presentation, we formally define

$$(2.5) \qquad a_{ij}(z) = \sum_{k \geq 0} \alpha_{ij}^{(k)} z^k, \qquad b_i(z) = \sum_{k \geq 0} \beta_i^{(k)} z^k.$$

A black node preceded by another black node is interpreted as $\alpha_{ij}^{(0)}$, whereas a black root is interpreted as $\beta_i^{(0)}$. This is exactly the same interpretation as for the underlying Runge–Kutta method. Moreover, k subsequent white nodes followed by a black node are interpreted as $\beta_i^{(k)}$ or $\alpha_{ij}^{(k)}$, respectively, depending on whether they appear at the root or not, respectively. This is seen directly from (2.5) with $z = -hA$. The order conditions up to order four are displayed in Table 1.

3. Analytical framework. Our analysis below will be based on an abstract formulation of (1.1) as an evolution equation in a Banach space $(X, \|\cdot\|)$. Let $\mathcal{D}(A)$ denote the domain of A in X. Our basic assumptions on the operator A are those of [8].

Assumption 1. Let $A : \mathcal{D}(A) \to X$ be sectorial; i.e., A is a densely defined and closed linear operator on X satisfying the resolvent condition

$$(3.1) \qquad \|(\lambda I - A)^{-1}\|_{X \leftarrow X} \leq \frac{M}{|\lambda - a|}$$

on the sector $\{\lambda \in \mathbb{C} : \vartheta \leq |\arg(\lambda - a)| \leq \pi, \ \lambda \neq a\}$ for $M \geq 1$, $a \in \mathbb{R}$, and $0 < \vartheta < \pi/2$.

Under this assumption, the operator $-A$ is the infinitesimal generator of an analytic semigroup $\{e^{-tA}\}_{t \geq 0}$. For $\omega > -a$, the fractional powers of $\widetilde{A} = A + \omega I$ are well defined. The following stability bounds are proved in [10]. They are crucial in our analysis.

LEMMA 3.1. *Under Assumption 1 and for fixed $\omega > -a$, the following bounds hold uniformly on $0 \leq t \leq T$:*

$$(3.2a) \qquad \|e^{-tA}\|_{X \leftarrow X} + \|t^\gamma \widetilde{A}^\gamma e^{-tA}\|_{X \leftarrow X} \leq C, \qquad \gamma \geq 0,$$
$$(3.2b) \qquad \left\| hA \sum_{j=1}^{n-1} e^{-jhA} \right\|_{X \leftarrow X} \leq C.$$

The next lemma (often called Abel's partial summation) is a discrete version of the integration-by-parts formula. Its proof is straightforward.

LEMMA 3.2. *For $W_k = \sum_{j=0}^{k} w_j$ the following summation-by-parts formula holds:*

$$(3.3) \qquad \sum_{j=0}^{n-1} w_j v_{n-j} = W_{n-1} v_1 - \sum_{j=0}^{n-2} W_j (v_{n-j-1} - v_{n-j}).$$

TABLE 1
Order trees and nonstiff order conditions for exponential Runge–Kutta methods.

| No.	Tree	Order	Differential	Order condition
1		1	F	$\sum \beta_i^{(0)} = 1$
2		2	$g'F$	$\sum \beta_i^{(0)} \alpha_{ij}^{(0)} = \frac{1}{2}$
3		2	AF	$\sum \beta_i^{(1)} = \frac{1}{2}$
4		3	$g''(F,F)$	$\sum \beta_i^{(0)} \alpha_{ij}^{(0)} \alpha_{ik}^{(0)} = \frac{1}{3}$
5		3	$g'g'F$	$\sum \beta_i^{(0)} \alpha_{ij}^{(0)} \alpha_{jk}^{(0)} = \frac{1}{6}$
6		3	$g'AF$	$\sum \beta_i^{(0)} \alpha_{ij}^{(1)} = \frac{1}{6}$
7		3	$Ag'F$	$\sum \beta_i^{(1)} \alpha_{ij}^{(0)} = \frac{1}{6}$
8		3	AAF	$\sum \beta_i^{(2)} = \frac{1}{6}$
9		4	$g'''(F,F,F)$	$\sum \beta_i^{(0)} \alpha_{ij}^{(0)} \alpha_{ik}^{(0)} \alpha_{il}^{(0)} = \frac{1}{4}$
10		4	$g''(g'F,F)$	$\sum \beta_i^{(0)} \alpha_{ij}^{(0)} \alpha_{ik}^{(0)} \alpha_{kl}^{(0)} = \frac{1}{8}$
11		4	$g''(AF,F)$	$\sum \beta_i^{(0)} \alpha_{ij}^{(0)} \alpha_{ik}^{(1)} = \frac{1}{8}$
12		4	$g'g''(F,F)$	$\sum \beta_i^{(0)} \alpha_{ij}^{(0)} \alpha_{jk}^{(0)} \alpha_{jl}^{(0)} = \frac{1}{12}$
13		4	$Ag''(F,F)$	$\sum \beta_i^{(1)} \alpha_{ij}^{(0)} \alpha_{ik}^{(0)} = \frac{1}{12}$
14		4	$g'g'g'F$	$\sum \beta_i^{(0)} \alpha_{ij}^{(0)} \alpha_{jk}^{(0)} \alpha_{kl}^{(0)} = \frac{1}{24}$
15		4	$g'g'AF$	$\sum \beta_i^{(0)} \alpha_{ij}^{(0)} \alpha_{jk}^{(1)} = \frac{1}{24}$
16		4	$g'Ag'F$	$\sum \beta_i^{(0)} \alpha_{ij}^{(1)} \alpha_{jk}^{(0)} = \frac{1}{24}$
17		4	$Ag'g'F$	$\sum \beta_i^{(1)} \alpha_{ij}^{(0)} \alpha_{jk}^{(0)} = \frac{1}{24}$
18		4	$g'AAF$	$\sum \beta_i^{(0)} \alpha_{ij}^{(2)} = \frac{1}{24}$
19		4	$Ag'AF$	$\sum \beta_i^{(1)} \alpha_{ij}^{(1)} = \frac{1}{24}$
20		4	$AAg'F$	$\sum \beta_i^{(2)} \alpha_{ij}^{(0)} = \frac{1}{24}$
21		4	$AAAF$	$\sum \beta_i^{(3)} = \frac{1}{24}$

The stability estimate (3.2a) enables us to define the bounded operators

$$(3.4) \qquad \varphi_j(-tA) = \frac{1}{t^j} \int_0^t \mathrm{e}^{-(t-\tau)A} \frac{\tau^{j-1}}{(j-1)!} \, \mathrm{d}\tau, \qquad j \geq 1.$$

We note for later use that $\varphi_0(z) = \mathrm{e}^z$ and

$$(3.5) \qquad \varphi_{k+1}(z) = \frac{\varphi_k(z) - 1/k!}{z}, \qquad \varphi_k(0) = \frac{1}{k!}, \qquad k \geq 0.$$

Our basic assumptions on g are those of [8] and [22]. We thus choose $0 \leq \alpha < 1$ and define $V = \mathcal{D}(\widetilde{A}^\alpha) \subset X$, where $\widetilde{A}$ denotes the shifted operator $\widetilde{A} = A + \omega I$ with $\omega > -a$. The linear space V is a Banach space with norm $\|v\|_V = \|\widetilde{A}^\alpha v\|$. Note that V does not depend on ω, since different choices of ω lead to equivalent norms. Our main hypothesis on the nonlinearity g is the following.

Assumption 2. Let $g : [0, T] \times V \to X$ be locally Lipschitz-continuous in a strip along the exact solution u. Thus there exists a real number $L(R, T)$ such that

$$(3.6) \qquad \|g(t, v) - g(t, w)\| \leq L\|v - w\|_V$$

for all $t \in [0, T]$ and $\max(\|v - u(t)\|_V, \|w - u(t)\|_V) \leq R$.

Example. It is well known that reaction-diffusion equations fit into this abstract framework, as well as the incompressible Navier–Stokes equations in two and three space dimensions; see, e.g., [8, Chapter 3] and [17, section 7.3].

For high-order convergence results, we have to assume more regularity.

Assumption 3. We suppose that (1.1) possesses a sufficiently smooth solution $u : [0, T] \to V$ with derivatives in V, and that $g : [0, T] \times V \to X$ is sufficiently often Fréchet differentiable in a strip along the exact solution. All occurring derivatives are supposed to be uniformly bounded.

Note that, under the above assumption, the composition

$$f : [0, T] \to X : t \mapsto f(t) = g(t, u(t))$$

is a smooth mapping, too. This will be used frequently.

4. Convergence results for exponential methods. In this section, we discuss the exponential counterparts of classical Runge–Kutta methods and study their convergence properties for the semilinear problem (1.1). More precisely, we consider methods with

$$(4.1) \qquad \chi(z) = \mathrm{e}^z \qquad \text{and} \qquad \chi_i(z) = \mathrm{e}^{c_i z}, \quad 1 \leq i \leq s.$$

Our main interest lies in *explicit* methods for which, due to $c_1 = 0$,

$$(4.2) \qquad \chi_1(z) = 1 \qquad \text{and} \qquad a_{ij}(z) = 0, \qquad 1 \leq i \leq j \leq s.$$

Implicit methods have been analyzed in detail in our recent paper [10]. The scheme (2.1) satisfying (4.1) and (4.2) is called an *explicit exponential Runge–Kutta method* henceforth. For the coefficients of the exponential Runge–Kutta method (2.1) we assume stability assumptions similar to (3.2a)

$$(4.3) \qquad \|\phi(-tA)\|_{X \leftarrow X} + \left\| t^\gamma \widetilde{A}^\gamma \phi(-tA) \right\|_{X \leftarrow X} \leq C, \qquad 0 \leq \gamma \leq 1,$$

for $\phi = b_i$ or $\phi = a_{ij}$, $i, j = 1, \ldots, s$. This assumption is satisfied by all methods considered below, since $b_i(z)$ and $a_{ij}(z)$ are (linear) combinations of the functions $\varphi_k(z)$ and $\varphi_k(c_l z)$, respectively.

4.1. Error recursion and representation of the defects. In order to simplify the notation, we again set $f(t) = g(t, u(t))$. Our proofs are heavily based on the representation of the exact solution by the variation-of-constants formula

$$(4.4) \qquad u(t_n + \theta h) = e^{-\theta h A} u(t_n) + \int_0^{\theta h} e^{-(\theta h - \tau)A} f(t_n + \tau) \, d\tau.$$

We expand f into a Taylor series with remainder in integral form to get

$$(4.5) \qquad f(t_n + \tau) = \sum_{j=1}^{q} \frac{\tau^{j-1}}{(j-1)!} f^{(j-1)}(t_n) + \int_0^{\tau} \frac{(\tau - \sigma)^{q-1}}{(q-1)!} f^{(q)}(t_n + \sigma) \, d\sigma.$$

On the one hand, inserting this into the right-hand side of (4.4) yields

$$(4.6)$$
$$u(t_n + c_i h) = e^{-c_i h A} u(t_n) + \sum_{j=1}^{q_i} (c_i h)^j \varphi_j(-c_i h A) f^{(j-1)}(t_n)$$
$$+ \int_0^{c_i h} e^{-(c_i h - \tau)A} \int_0^{\tau} \frac{(\tau - \sigma)^{q_i - 1}}{(q_i - 1)!} f^{(q_i)}(t_n + \sigma) \, d\sigma \, d\tau.$$

On the other hand, inserting the exact solution into the numerical scheme gives

$$(4.7a) \qquad u(t_n + c_i h) = e^{-c_i h A} u(t_n) + h \sum_{j=1}^{i-1} a_{ij}(-hA) f(t_n + c_j h) + \Delta_{ni},$$

$$(4.7b) \qquad u(t_{n+1}) = e^{-hA} u(t_n) + h \sum_{i=1}^{s} b_i(-hA) f(t_n + c_i h) + \delta_{n+1}$$

with defects Δ_{ni} and δ_{n+1}. Substituting (4.5) into (4.7a), we obtain

$$(4.8)$$
$$u(t_n + c_i h) = e^{-c_i h A} u(t_n) + h \sum_{k=1}^{i-1} a_{ik}(-hA) \sum_{j=1}^{q_i} \frac{(c_k h)^{j-1}}{(j-1)!} f^{(j-1)}(t_n)$$
$$+ h \sum_{k=1}^{i-1} a_{ik}(-hA) \int_0^{c_k h} \frac{(c_k h - \sigma)^{q_i - 1}}{(q_i - 1)!} f^{(q_i)}(t_n + \sigma) \, d\sigma + \Delta_{ni}.$$

Subtracting (4.6) from (4.8) gives the following explicit representation of the defects,

$$(4.9) \qquad \Delta_{ni} = \sum_{j=1}^{q_i} h^j \psi_{j,i}(-hA) f^{(j-1)}(t_n) + \Delta_{ni}^{[q_i]},$$

with remainders $\Delta_{ni}^{[q_i]}$ and with

$$(4.10) \qquad \psi_{j,i}(-hA) = \varphi_j(-c_i h A) c_i^j - \sum_{k=1}^{i-1} a_{ik}(-hA) \frac{c_k^{j-1}}{(j-1)!}.$$

Similarly, we get for the defects at time t_{n+1}

$$(4.11) \qquad \delta_{n+1} = \sum_{j=1}^{q} h^j \psi_j(-hA) f^{(j-1)}(t_n) + \delta_{n+1}^{[q]},$$

where

$$(4.12) \qquad \psi_j(-hA) = \varphi_j(-hA) - \sum_{k=1}^{s} b_k(-hA)\frac{c_k^{j-1}}{(j-1)!}.$$

For the remainders in (4.9) and (4.11), we have the following estimate.

LEMMA 4.1. *Let* $0 < \nu \le 1$ *and* $\widetilde{A}^{\nu-1}f^{(r)} \in L^\infty(0, T; V)$. *Then,*

$$(4.13a) \qquad h^{1-\nu}\|\Delta_{ni}^{[r]}\|_V + \|\widetilde{A}^{\nu-1}\Delta_{ni}^{[r]}\|_V \le Ch^{r+1} \sup_{0 \le \tau \le 1} \|\widetilde{A}^{\nu-1}f^{(r)}(t_n + \tau h)\|_V,$$

$$(4.13b) \qquad \left\|\sum_{j=0}^{n-1} \mathrm{e}^{-jhA}\delta_{n-j}^{[r]}\right\|_V \le Ch^r \sup_{0 \le t \le t_n} \|\widetilde{A}^{\nu-1}f^{(r)}(t)\|_V$$

holds with a constant C, *uniformly in* $0 \le t_n \le T$.

Proof. Both estimates follow at once from the stability bound

$$\left\|t^\gamma\widetilde{A}^\gamma\mathrm{e}^{-tA}\right\|_{V \leftarrow V} + \left\|t^\gamma\widetilde{A}^\gamma\phi(-tA)\right\|_{V \leftarrow V} \le C, \qquad 0 \le \gamma \le 1,$$

for $\phi = b_i$ or $\phi = a_{ij}$, $i, j = 1, \dots, s$. The latter is a consequence of (3.2a) and (4.3), respectively. □

Let $e_n = u_n - u(t_n)$ and $E_{ni} = U_{ni} - u(t_n + c_ih)$ denote the differences between the numerical and the exact solutions. Subtracting (4.7) from the numerical method (2.1) satisfying (4.1) and (4.2) gives the error recursion

$$(4.14a) \quad E_{ni} = \mathrm{e}^{-c_ihA}e_n + h\sum_{j=1}^{i-1} a_{ij}(-hA)\Big(g(t_n + c_jh, U_{nj}) - f(t_n + c_jh)\Big) - \Delta_{ni},$$

$$(4.14b) \quad e_{n+1} = \mathrm{e}^{-hA}e_n + h\sum_{i=1}^{s} b_i(-hA)\Big(g(t_n + c_ih, U_{ni}) - f(t_n + c_ih)\Big) - \delta_{n+1}.$$

We will derive bounds for these errors.

4.2. Convergence of the exponential Euler method. For $s = 1$, the only reasonable choice is the exponential form of Euler's method. Applied to (1.1), it is

$$(4.15) \qquad u_{n+1} = \mathrm{e}^{-hA}u_n + h\varphi_1(-hA)g(t_n, u_n).$$

For this method, we have the following convergence result.

THEOREM 4.2. *Let the initial value problem* (1.1) *satisfy Assumptions* 1–2 *and consider for its numerical solution the exponential Euler method* (4.15). *Further assume that* $f : [0, T] \to X$ *is differentiable and that* $\beta \in (0, 1]$ *is such that* $\widetilde{A}^{\beta-1}f' \in L^\infty(0, T; V)$. *Then, the error bound*

$$\|u_n - u(t_n)\|_V \le C \cdot h \sup_{0 \le t \le t_n} \|\widetilde{A}^{\beta-1}f'(t)\|_V$$

holds uniformly in $0 \le nh \le T$. *The constant* C *depends on* T, *but it is independent of* n *and* h.

Proof. The exponential Euler method satisfies the error recursion

$$(4.16) \qquad e_{n+1} = \mathrm{e}^{-hA}e_n + h\varphi_1(-hA)\big(g(t_n, u_n) - f(t_n)\big) - \delta_{n+1}$$

with defects $\delta_{n+1} = \delta_{n+1}^{[1]}$ given by (4.7b) and (4.11). Solving recursion (4.16) gives

$$e_n = h \sum_{j=0}^{n-1} \mathrm{e}^{-(n-j-1)hA} \varphi_1(-hA)\big(g(t_j, u_j) - f(t_j)\big) - \sum_{j=0}^{n-1} \mathrm{e}^{-jhA} \delta_{n-j}.$$

Using (3.2a), Assumption 2, and Lemma 4.1, we may estimate this in V by

$$\|e_n\|_V \leq Ch \sum_{j=0}^{n-2} t_{n-j-1}^{-\alpha} \|e_j\|_V + Ch^{1-\alpha} \|e_{n-1}\|_V + Ch \sup_{0 \leq t \leq t_n} \|\widetilde{A}^{\beta-1} f'(t)\|_V.$$

The application of a discrete Gronwall lemma [10, Lemma 4] now concludes the proof. □

Remark. The above theorem can also be deduced from [10], since the exponential Euler method is a collocation method with $s = 1$ and $c_1 = 0$.

4.3. Convergence results for second-order methods. We first derive a bound for the errors of the internal stages. Due to (2.2) and (4.1), we always have $\psi_{1,j} = 0$. From (4.9) and (4.14a) we thus get, with the help of Assumption 2,

$$\|E_{ni}\|_V \leq C \|e_n\|_V + Ch^{1-\alpha} \max_{2 \leq j \leq i-1} \|E_{nj}\|_V + \|\Delta_{ni}^{[1]}\|_V.$$

Applying Lemma 4.1 then shows the a priori bound

(4.17) $$\|E_{ni}\|_V \leq C \|e_n\|_V + Ch^{1+\nu} \sup_{0 \leq \tau \leq 1} \|\widetilde{A}^{\nu-1} f'(t_n + \tau h)\|_V.$$

For second-order methods, we will satisfy the order conditions

(4.18) $$\psi_1(-hA) = 0, \qquad \psi_2(-hA) = 0$$

and take $q = 2$ in (4.11). We are now in the position to state the convergence theorem.

THEOREM 4.3. *Let the initial value problem* (1.1) *satisfy Assumptions 1 and 2, and consider for its solution an exponential Runge–Kutta method* (2.1) *satisfying* (4.1), (4.2), *and* (4.18). *Further assume that* $f : [0, T] \to X$ *is twice differentiable and that* $\beta, \kappa \in (0, 1]$ *are such that* $\widetilde{A}^{\beta-1} f' \in L^\infty(0, T; V)$ *and* $\widetilde{A}^{\kappa-1} f'' \in L^\infty(0, T; V)$. *Then, the error bound*

$$\|u_n - u(t_n)\|_V \leq C \cdot h^{1+\beta} \sup_{0 \leq t \leq t_n} \|\widetilde{A}^{\beta-1} f'(t)\|_V + C \cdot h^2 \sup_{0 \leq t \leq t_n} \|\widetilde{A}^{\kappa-1} f''(t)\|_V$$

holds uniformly in $0 \leq nh \leq T$. *The constant* C *depends on* T, *but it is independent of* n *and* h.

Remark. If $f', f'' \in L^\infty(0, T; X)$, the above theorem is applicable with $\beta = \kappa = 1 - \alpha$. For $\beta = 1$, the theorem yields order 2. Under the slightly weaker regularity assumptions $f'(0) \in V$ and $f'' \in L^1(0, T; V)$, we obtain an alternative second-order error bound

$$\|u_n - u(t_n)\|_V \leq C \cdot h^2 \left(\|f'(0)\|_V + \int_0^{t_n} \|f''(\tau)\|_V \, \mathrm{d}\tau \right).$$

This follows easily from the proof of Theorem 4.3.

Proof. Solving the error recursion (4.14b) in the same way as in the proof of Theorem 4.2 gives

$$\|e_n\|_V \le Ch^{1-\alpha}\|E_{n-1}\|_V + Ch\sum_{j=0}^{n-2} t_{n-j-1}^{-\alpha}\|E_j\|_V + \left\|\sum_{j=0}^{n-1} \mathrm{e}^{-jhA}\delta_{n-j}\right\|_V$$

with $\|E_j\|_V = \max_{2\le k\le s}\|E_{jk}\|_V$. After inserting the bounds (4.17) and (4.13b), the proof is concluded by applying a discrete Gronwall lemma. $\square$

If $g : [0,T] \times V \to X$ is twice differentiable, its derivatives

$$J_n = \frac{\partial g}{\partial u}\bigl(t_n, u(t_n)\bigr), \qquad K_n = \frac{\partial^2 g}{\partial t\partial u}\bigl(t_n, u(t_n)\bigr)$$

are bounded operators from V to X.

LEMMA 4.4. *Under Assumption 3, we have*

(4.19a) $$g(t_n + c_ih, U_{ni}) - f(t_n + c_ih) = J_nE_{ni} + c_ihK_nE_{ni} + Q_{ni},$$

(4.19b) $$g(t_n, u_n) - f(t_n) = J_ne_n + Q_n$$

with remainders Q_{ni} and Q_n satisfying the bounds

$$\|Q_{ni}\| \le C\cdot\bigl(h^2 + \|E_{ni}\|_V\bigr)\|E_{ni}\|_V, \qquad \|Q_n\| \le C\cdot\|e_n\|_V^2,$$

as long as the errors E_{ni} and e_n remain in a sufficiently small neighborhood of 0.

Proof. Using Taylor series expansion, we get

$$g(t_n + c_ih, U_{ni}) - f(t_n + c_ih) = \frac{\partial g}{\partial u}\bigl(t_n + c_ih, u(t_n + c_ih)\bigr)E_{ni}$$
$$+ \int_0^1 (1-\tau)\frac{\partial^2 g}{\partial u^2}\bigl(t_n + c_ih, u(t_n + c_ih) + \tau E_{ni}\bigr)(E_{ni}, E_{ni})\,\mathrm{d}\tau.$$

Expanding the first term on the right-hand side at t_n yields the desired result. $\square$

Inserting (4.19a) into the recursion (4.14b) shows that the main contribution of the defects to the global error is given by the term

(4.20) $$h\sum_{j=0}^{n-1} \mathrm{e}^{-jhA}\sum_{i=1}^{s} b_i(-hA)J_n\Delta_{n-j-1,i}^{[1]}.$$

Let $\gamma < 1$ and $0 \le \mu \le 1 - \beta$ be such that

(4.21) $$\bigl\|\widetilde{A}^{-\gamma}J_n\widetilde{A}^{\mu}\bigr\|_{V\leftarrow V} \le C.$$

This estimate holds trivially for $\gamma = \alpha$ and $\mu = 0$. But there are more favorable situations in which $\mu > 0$. Then, the expression (4.20) is bounded by

(4.22) $$C\cdot h^{1+\beta+\mu}\sup_{0\le t\le t_n}\|\widetilde{A}^{\beta-1}f'(t)\|_V,$$

which slightly improves the error bound of the theorem. We do not elaborate this point here further.

4.4. Convergence results for higher-order methods. An explicit expansion of E_{ni} in terms of Δ_{ni} and e_n is easily obtained with the help of Lemma 4.4 by inserting the expressions of the lemma recursively into (4.14a). Depending on the size of s and α, however, this expansion will consist of a great number of terms that all give rise to order conditions for the method. For example, the arising term

$$(4.23) \qquad h^{\ell+2} \sum_{j_1=1}^{i-1} a_{ij_1}(-hA)J_n \cdots \sum_{j_\ell=1}^{j_{\ell-1}} a_{j_{\ell-1}j_\ell}(-hA)J_n \cdot \psi_{2,j_\ell}(-hA)f'(t_n)$$

has classical order $\ell + 2$ and can be neglected for $\ell \geq 2$ in a fourth-order method. In our context, however, it has only order $1 + (\ell + 1)(1 - \alpha)$, and this might be a small number, even for large ℓ. In that case, the term can no longer be neglected.

To keep our presentation simple, we will consider in the remainder of this section only the case $\alpha = 0$. It is therefore no longer necessary to distinguish between the spaces V and X.

LEMMA 4.5. *Under the assumptions of Lemma 4.4 and $\alpha = 0$, there exist bounded operators $\mathcal{N}_{ni}(e_n)$ on X such that*

$$E_{ni} = \mathcal{N}_{ni}(e_n)e_n - h^2\psi_{2,i}(-hA)f'(t_n) - h^3\psi_{3,i}(-hA)f''(t_n)$$
$$- h^3\sum_{j=2}^{i-1} a_{ij}(-hA)J_n\psi_{2,j}(-hA)f'(t_n) + h^4\mathcal{R}_{ni},$$

with uniformly bounded remainders $\|\mathcal{R}_{ni}\| \leq C$.

Proof. The formula follows easily from recursion (4.14a), the representation of the defects (4.9), and from Lemma 4.4 by an induction argument. □

An important consequence of the above lemma is the following representation of the errors e_n. It is the key result for obtaining the stiff order conditions.

LEMMA 4.6. *Under the assumptions of Lemma 4.4 and $\alpha = 0$, there exist uniformly bounded operators $\mathcal{N}_n(e_n)$ on X such that the global errors e_n satisfy the recursion*

$$e_{n+1} = e^{-hA}e_n + h\mathcal{N}_n(e_n)e_n - h^2\psi_2(-hA)f'(t_n)$$
$$- h^3\psi_3(-hA)f''(t_n) - h^3\sum_{i=1}^{s} b_i(-hA)J_n\psi_{2,i}(-hA)f'(t_n)$$
$$- h^4\psi_4(-hA)f'''(t_n) - h^4\sum_{i=1}^{s} b_i(-hA)J_n\psi_{3,i}(-hA)f''(t_n)$$
$$(4.24) \qquad - h^4\sum_{i=1}^{s} b_i(-hA)J_n\sum_{j=2}^{i-1} a_{ij}(-hA)J_n\psi_{2,j}(-hA)f'(t_n)$$
$$- h^4\sum_{i=1}^{s} b_i(-hA)c_iK_n\psi_{2,j}(-hA)f'(t_n) + h^5\mathcal{R}_n,$$

with uniformly bounded remainders $\|\mathcal{R}_n\| \leq C$.

Proof. The formula follows easily from recursion (4.14b), the representation of the defects (4.11), and Lemma 4.5. □

The stiff order conditions can easily be identified in (4.24). For clarity, we have collected them in Table 2. With these preparations, we are now in the position to formulate a more general convergence result.

TABLE 2
Stiff order conditions for explicit exponential Runge–Kutta methods for $\alpha = 0$. Here J and K denote arbitrary bounded operators on X. The functions ψ_i and $\psi_{k,\ell}$ are defined in (4.12) and (4.10), respectively.

No.	Order	Order condition
1	1	$\psi_1(-hA) = 0$
2	2	$\psi_2(-hA) = 0$
3	2	$\psi_{1,i}(-hA) = 0$
4	3	$\psi_3(-hA) = 0$
5	3	$\displaystyle\sum_{i=1}^{s} b_i(-hA)J\psi_{2,i}(-hA) = 0$
6	4	$\psi_4(-hA) = 0$
7	4	$\displaystyle\sum_{i=1}^{s} b_i(-hA)J\psi_{3,i}(-hA) = 0$
8	4	$\displaystyle\sum_{i=1}^{s} b_i(-hA)J\sum_{j=2}^{i-1} a_{ij}(-hA)J\psi_{2,j}(-hA) = 0$
9	4	$\displaystyle\sum_{i=1}^{s} b_i(-hA)c_i K\psi_{2,i}(-hA) = 0$

THEOREM 4.7. *Let the initial value problem (1.1) satisfy Assumptions 1–3 with $\alpha = 0$, and consider for its numerical solution an explicit exponential Runge–Kutta method (2.1) satisfying (4.1) and (4.2). For $2 \le p \le 4$, assume that the order conditions of Table 2 hold up to order $p - 1$ and that $\psi_p(0) = 0$. Further assume that the remaining conditions of order p hold in a weaker form with $b_i(0)$ instead of $b_i(-hA)$ for $2 \le i \le s$. Then, the numerical solution u_n satisfies the error bound*

$$\|u_n - u(t_n)\| \le C \cdot h^p,$$

uniformly in $0 \le nh \le T$. The constant C depends on T, but it is independent of n and h.

Proof. Inserting the order conditions into the recursion of Lemma 4.6 yields

$$e_{n+1} = e^{-hA}e_n + h\mathcal{N}_n(e_n)e_n + h^p\mathcal{T}_n + h^{p+1}\mathcal{R}_n$$

with bounded remainders $\mathcal{R}_n$ depending on p. Here, $\mathcal{T}_n$ denotes the terms multiplying h^p in Lemma 4.6. Solving the above error recursion gives

$$e_n = h\sum_{j=0}^{n-1} e^{-(n-j)hA}\mathcal{N}_j(e_j)e_j + h^p\sum_{j=0}^{n-1} e^{-jhA}\mathcal{T}_{n-j-1} + h^{p+1}\sum_{j=0}^{n-1} e^{-jhA}\mathcal{R}_{n-j-1}.$$

In order to bound the second term on the right-hand side, we use the assumptions on the conditions of order p and apply Lemma 4.8 below. Using further the stability estimate (3.2a) and the bounds for $\mathcal{R}_j$ and for $\mathcal{N}_j(e_j)$ finally yields

$$\|e_n\| \le Ch\sum_{j=0}^{n-1}\|e_j\| + Ch^p.$$

Thus, an application of the classical Gronwall lemma concludes the proof. □

The following lemma was used in the above proof.

LEMMA 4.8. *Under the above assumptions, let $\varrho_i : [0, T] \to X$ for $1 \leq i \leq s$ denote differentiable functions with bounded derivatives. Then*

$$(4.25) \qquad \left\| \sum_{j=0}^{n-1} \mathrm{e}^{-jhA} \sum_{i=1}^{s} \big(b_i(-hA) - b_i(0) \big) \varrho_i(t_{n-j-1}) \right\| \leq C.$$

Proof. We first note that there exist bounded operators $\widetilde{b}_i(-hA)$ with

$$b_i(-hA) - b_i(0) = hA \cdot \widetilde{b}_i(-hA).$$

The bound (4.25) now follows at once from Lemma 3.2 with $w_j = \mathrm{e}^{-jhA} hA \cdot \widetilde{b}_i(-hA)$ and $v_j = \varrho_i(t_{j-1})$ by using the stability bound (3.2b). $\square$

Remark. The proof of Theorem 4.7 does not extend immediately to variable step sizes. The reason for this lies in the use of the summation-by-parts formula (3.3). Assuming, however, that the method satisfies the conditions of order p in the strong sense of Table 2, then Lemma 4.8 is no longer needed. In that case, the theorem obviously holds for variable step sizes, too.

4.5. Existence of explicit methods of arbitrarily high order. In our recent paper [10] we have shown that, under the above assumptions, an s-stage exponential Runge–Kutta method of collocation type with coefficients $\widehat{a}_{ij}(-hA)$ and $\widehat{b}_i(-hA)$ satisfies the error bound

$$\|\widehat{u}_n - u(t_n)\|_V \leq C\, h^s \sup_{0 \leq t \leq T} \|f^{(s)}(t)\|,$$

uniformly on $0 \leq t_n \leq T$. It is further shown there that the equations for the internal stages can be solved by fixed-point iteration,

$$\widehat{U}_{ni}^{(k)} = \mathrm{e}^{-c_i hA} \widehat{u}_n + h \sum_{i=1}^{s} \widehat{a}_{ij}(-hA)\, g\big(t_n + c_j h, \widehat{U}_{nj}^{(k-1)}\big), \qquad \widehat{U}_{nj}^{(0)} = \widehat{u}_n.$$

For $\alpha = 0$, we obviously gain one power of h in each iteration. Performing s iterations and setting $U_{ni} = \widehat{U}_{ni}^{(s)}$, $1 \leq i \leq s$, and

$$u_{n+1} = \mathrm{e}^{-hA} u_n + h \sum_{i=1}^{s} \widehat{b}_i(-hA)\, g\big(t_n + c_j h, U_{nj}\big)$$

thus defines an *explicit* exponential Runge–Kutta method of order s with s^2 stages. The construction shows that there exist explicit exponential Runge–Kutta methods of arbitrarily high order. For general α, however, we gain only $h^{1-\alpha}$ in each iteration. Therefore, a lot of explicit stages might be necessary for obtaining order s.

5. A discussion of explicit methods of orders up to four. In this section, we consider some examples of methods up to order four. Since the first-order exponential Euler method has already been analyzed in section 4.2, we commence here with second-order methods. In the Butcher tableaus below, we use the abbreviations

$$(5.1) \qquad \varphi_{i,j} = \varphi_{i,j}(-hA) = \varphi_i(-c_j hA), \qquad 2 \leq j \leq s.$$

5.1. Second-order methods. Second-order methods require two internal stages at least. For two stages, the order conditions are

$$b_1(-hA) + b_2(-hA) = \varphi_1(-hA), \tag{5.2a}$$

$$b_2(-hA)c_2 = \varphi_2(-hA), \tag{5.2b}$$

$$a_{21}(-hA) = c_2\varphi_1(-c_2hA). \tag{5.2c}$$

A straightforward elimination leads to the following one-parameter family of exponential Runge–Kutta methods

$$(5.3) \qquad \begin{array}{c|cc} 0 & & \\ c_2 & c_2\,\varphi_{1,2} & \\ \hline & \varphi_1 - \frac{1}{c_2}\varphi_2 & \frac{1}{c_2}\varphi_2 \end{array}.$$

The coefficients are displayed as usual in a Butcher tableau. It is also possible to omit the function φ_2 by weakening condition (5.2b) to $b_2(0)c_2 = \varphi_2(0) = \frac{1}{2}$. This yields another one-parameter family of methods

$$(5.4) \qquad \begin{array}{c|cc} 0 & & \\ c_2 & c_2\,\varphi_{1,2} & \\ \hline & (1 - \frac{1}{2c_2})\varphi_1 & \frac{1}{2c_2}\varphi_1 \end{array}.$$

Note that the choice $c_2 = \frac{1}{2}$ yields $b_1 = 0$.

Methods (5.3) and (5.4) have been proposed already by Strehmel and Weiner [25, Example 4.2.2] in the context of adaptive Runge–Kutta methods, where the functions φ_j are usually approximated by certain rational functions. It is shown in [25, Section 4.5.3] that both methods are B-consistent of order one.

Method (5.3) satisfies the assumptions of Theorem 4.3 and thus converges with order $1 + \beta$, in general. Method (5.4) can be analyzed in a similar way, as it differs from (5.3) in the choice of the quadrature rule for u_{n+1} only. The defects at the grid points now have the form

$$(5.5) \qquad \begin{aligned} \delta_{n+1} &= \frac{h^2}{2}\big(2\varphi_2(-hA) - \varphi_1(-hA)\big)f'\left(t_n + \frac{h}{2}\right) \\ &\quad + \int_0^h \mathrm{e}^{-(h-\tau)A}\int_{h/2}^\tau (\tau - \xi)f''(t_n + \xi)\,\mathrm{d}\xi. \end{aligned}$$

Since $2\varphi_2(0) - \varphi_1(0) = 0$, the first term of (5.5) contributes with

$$(5.6) \qquad C \cdot h^{1+\beta}\left(\|\widetilde{A}^{\beta-1}f'(0)\|_V + \int_0^{t_n}\|\widetilde{A}^{\beta-1}f''(t)\|_V\,\mathrm{d}t\right)$$

to the global error. This is seen with the help of Lemma 3.2. Thus, Theorem 4.3 holds with the additional error term (5.6) for the modified method (5.4), too. In particular, we get a second-order error bound for $\beta = 1$. Note, however, that (5.6) cannot be improved under a condition of the type (4.21). For situations in which $f'(t), f''(t) \notin V$, method (5.3) is therefore preferable to method (5.4), which can be affected by an order reduction; see also Figure 6.3 below.

5.2. Third-order methods. We will continue with 3-stage methods. In the following, we assume $\alpha = 0$. The order conditions for 3-stage methods are

$$(5.7a) \qquad b_1(-hA) + b_2(-hA) + b_3(-hA) = \varphi_1(-hA),$$

$$(5.7b) \qquad b_2(-hA)c_2 + b_3(-hA)c_3 = \varphi_2(-hA),$$

$$(5.7c) \qquad a_{21}(-hA) = c_2\varphi_1(-c_2hA),$$

$$(5.7d) \qquad a_{31}(-hA) + a_{32}(-hA) = c_3\varphi_1(-c_3hA),$$

$$(5.7e) \qquad b_2(-hA)c_2^2 + b_3(-hA)c_3^2 = 2\varphi_3(-hA),$$

$$(5.7f) \qquad b_2(-hA)Jc_2^2\varphi_2(-c_2hA) + b_3(-hA)J\psi_{2,3} = 0,$$

where

$$\psi_{2,3} = c_3^2\varphi_2(-c_3hA) - c_2a_{32}(-hA).$$

Condition (5.7f) can be satisfied by $b_2 = 0$ and $\psi_{2,3} = 0$ or $b_2 = \gamma b_3$ and $c_2^2\varphi_{2,2} + \gamma\psi_{2,3} = 0$. However, both choices contradict conditions (5.7b) and (5.7e). We thus weaken (5.7e) to

$$(5.7g) \qquad b_2(0)c_2^2 + b_3(0)c_3^2 = 2\varphi_3(0) = \frac{1}{3}.$$

The choice $b_2 = 0$ leads to the following one-parameter family of third-order methods:

$$(5.8) \qquad \begin{array}{c|ccc} 0 & & & \\ c_2 & c_2\varphi_{1,2} & & \\ \frac{2}{3} & \frac{2}{3}\varphi_{1,3} - \frac{4}{9c_2}\varphi_{2,3} & \frac{4}{9c_2}\varphi_{2,3} & \\ \hline & \varphi_1 - \frac{3}{2}\varphi_2 & 0 & \frac{3}{2}\varphi_2 \end{array}.$$

The other choice $b_2 = \gamma b_3$ leads to the two-parameter family of methods of order three

$$(5.9) \qquad \begin{array}{c|ccc} 0 & & & \\ c_2 & c_2\varphi_{1,2} & & \\ c_3 & c_3\varphi_{1,3} - a_{32} & \gamma c_2\varphi_{2,2} + \frac{c_3^2}{c_2}\varphi_{23} & \\ \hline & \varphi_1 - b_2 - b_3 & \frac{\gamma}{\gamma c_2 + c_3}\varphi_2 & \frac{1}{\gamma c_2 + c_3}\varphi_2 \end{array},$$

where γ, c_2, and c_3 have to satisfy the restriction

$$(5.10) \qquad 2(\gamma c_2 + c_3) = 3(\gamma c_2^2 + c_3^2).$$

Another possibility is to weaken (5.7f) to

$$(5.11) \qquad b_2(0)c_2^2\varphi_2(-c_2hA) + b_3(0)\big(c_3^2\varphi_2(-c_3hA) - c_2a_{32}(-hA)\big) = 0.$$

The order conditions of the underlying Runge–Kutta method of order three show that

$$b_2(0) = \frac{2 - 3c_3}{6c_2(c_2 - c_3)}, \qquad b_3(0) = \frac{2 - 3c_2}{6c_3(c_3 - c_2)};$$

see [7, Exercise II.1.4]. Here, we have to choose $c_2 \neq 2/3$ and $c_2 \neq c_3$ except for $c_2 = c_3 = 2/3$ where $b_2(0) + b_3(0) = 3/4$.

A three-parameter family of methods that involve φ_1 and φ_2 only is given by

$$(5.12) \qquad \begin{array}{c|ccc} 0 & & & \\ c_2 & c_2\varphi_{1,2} & & \\ c_3 & c_3\varphi_{1,3} - a_{32} & \frac{c_3^2}{c_2}\varphi_{2,3} - \frac{2-3c_3}{2-3c_2}c_3\varphi_{2,2} & \\ \hline & \varphi_1 - b_2 - b_3 & \alpha_2\varphi_1 + \beta_2\varphi_2 & \alpha_3\varphi_1 + \beta_3\varphi_2 \end{array} \quad .$$

In addition to c_2 and c_3, one of the coefficients α_i, β_i can be chosen arbitrarily, and the remaining ones are determined by the linear system

$$c_2\alpha_2 + c_3\alpha_3 = 0, \qquad \alpha_3 + \frac{1}{2}\beta_3 = b_3(0), \qquad c_2\beta_2 + c_3\beta_3 = 1.$$

Note that for $\alpha_2 = 0$ and $\beta_2 = \gamma\beta_3$ we recover condition (5.10) and obtain the scheme (5.9). Setting $\alpha_2 = \beta_2 = 0$ leads to $b_2(-hA) = 0$ and the condition $c_3 = 2/3$, which results in the scheme (5.8).

We next discuss some related methods which can be found in the literature.

Strehmel and Weiner [25, Example 4.5.4] proved that for a 3-stage adaptive Runge–Kutta method with second-order B-consistency, the condition $b_2 = 0$ is necessary. They proposed the following family of such methods:

$$\begin{array}{c|ccc} 0 & & & \\ c_2 & c_2\varphi_{1,2} & & \\ 1 & \varphi_{1,3} - \frac{1}{c_2}\varphi_{2,3} & \frac{1}{c_2}\varphi_{2,3} & \\ \hline & \varphi_1 - \varphi_2 & 0 & \varphi_2 \end{array} \quad .$$

These methods satisfy conditions (5.7a), (5.7b), (5.7c), and (5.7d), i.e., all conditions of Table 2 up to order two. However, the conditions (5.7f) and (5.7g) of order three are not satisfied, not even in a weak form. Therefore, these methods are of second order only. Since they are more expensive than the 2-stage methods proposed in the previous section, the latter should be preferred for semilinear parabolic problems.

Cox and Matthews [3] constructed a method called ETD3RK, which reads

$$(5.13) \qquad \begin{array}{c|ccc} 0 & & & \\ \frac{1}{2} & \frac{1}{2}\varphi_{1,2} & & \\ 1 & -\varphi_{1,3} & 2\varphi_{1,3} & \\ \hline & 4\varphi_3 - 3\varphi_2 + \varphi_1 & -8\varphi_3 + 4\varphi_2 & 4\varphi_3 - \varphi_2 \end{array} \quad .$$

This method uses φ_3 and satisfies conditions (5.7a), (5.7b), (5.7c), (5.7d), and (5.7g). However, condition (5.7f) is satisfied only in a very weak form (where all arguments are evaluated for $A = 0$). This leads to an order reduction to order two in the worst case. The same conditions are satisfied by ETD2RK3 from [3].

The method ETD2CF3 is a variant of the commutator-free Lie group method CF3 due to Celledoni, Marthinsen, and Owren [2]. It is given by

$$\begin{array}{c|ccc} 0 & & & \\ \frac{1}{3} & \frac{1}{3}\varphi_{1,2} & & \\ \frac{2}{3} & \frac{2}{3}\varphi_{1,3} - \frac{4}{3}\varphi_{2,3} & \frac{4}{3}\varphi_{2,3} & \\ \hline & \varphi_1 - \frac{9}{2}\varphi_2 + 9\varphi_3 & 6\varphi_2 - 18\varphi_3 & -\frac{3}{2}\varphi_2 + 9\varphi_3 \end{array} \quad .$$

This method satisfies (5.7a)–(5.7c) and weak forms of (5.7d) and (5.7f), where $b_i(-hA)$ is evaluated for $A = 0$. Therefore this method is of order three for $\alpha = 0$.

5.3. Fourth-order methods. Again we assume $\alpha = 0$. The order conditions for s-stage methods up to order four are

$$\text{(5.14a)} \qquad \sum_{i=1}^{s} b_i(-hA) = \varphi_1(-hA),$$

$$\text{(5.14b)} \qquad \sum_{i=2}^{s} b_i(-hA)c_i = \varphi_2(-hA),$$

$$\text{(5.14c)} \qquad \sum_{j=1}^{i-1} a_{ij}(-hA) = c_i\varphi_1(-c_ihA),$$

$$\text{(5.14d)} \qquad \sum_{i=2}^{s} b_i(-hA)c_i^2 = 2\varphi_3(-hA),$$

$$\text{(5.14e)} \qquad \sum_{i=2}^{s} b_i(-hA)J\left(\varphi_2(-c_ihA)c_i^2 - \sum_{j=2}^{i-1} a_{ij}(-hA)c_j\right) = 0,$$

$$\text{(5.14f)} \qquad \sum_{i=2}^{s} b_i(-hA)c_i^3 = 6\varphi_4(-hA),$$

$$\text{(5.14g)} \qquad \sum_{i=2}^{s} b_i(-hA)J\left(\varphi_3(-c_ihA)c_i^3 - \frac{1}{2}\sum_{j=2}^{i-1} a_{ij}(-hA)c_j^2\right) = 0,$$

$$\text{(5.14h)} \qquad \sum_{i=2}^{s} b_i(-hA)J\sum_{j=2}^{i-1} a_{ij}(-hA)J\left(\varphi_2(-c_jhA)c_j^2 - \sum_{k=2}^{j-1} a_{jk}(-hA)c_k\right) = 0,$$

$$\text{(5.14i)} \qquad \sum_{i=2}^{s} b_i(-hA)c_iK\left(\varphi_2(-c_ihA)c_i^2 - \sum_{j=2}^{i-1} a_{ij}(-hA)c_j\right) = 0.$$

From (5.14a), (5.14b), and (5.14d) we deduce that any fourth-order method has to involve φ_1, φ_2, and φ_3. By Theorem 4.7 it is sufficient to satisfy condition 6 of Table 2 in the weakened form $\psi_4(0) = 0$, i.e., to replace (5.14f) by

$$\text{(5.14j)} \qquad \sum_{i=2}^{s} b_i(0)c_i^3 = \frac{1}{4}.$$

Cox and Matthews [3] proposed the following exponential variant of the classical Runge–Kutta method:

$$\text{(5.15)} \qquad \begin{array}{c|cccc} 0 & & & & \\ \frac{1}{2} & \frac{1}{2}\varphi_{1,2} & & & \\ \frac{1}{2} & 0 & \frac{1}{2}\varphi_{1,3} & & \\ 1 & \frac{1}{2}\varphi_{1,3}(\varphi_{0,3}-1) & 0 & \varphi_{1,3} & \\ \hline & \varphi_1 - 3\varphi_2 + 4\varphi_3 & 2\varphi_2 - 4\varphi_3 & 2\varphi_2 - 4\varphi_3 & 4\varphi_3 - \varphi_2 \end{array} .$$

This method satisfies conditions 1–4 of Table 2, the weakened but sufficient condition 6 ($\psi_4(0) = 0$), but not conditions 5, 7, 8, and 9. However, it satisfies a weakened form of conditions 5 and 9 (because $\psi_{2,2}(0) + \psi_{2,3}(0) = 0$ and $\psi_{2,4}(0) = 0$), and a very weak form of conditions 7 and 8 (where all arguments are evaluated for $A = 0$). In the worst case, this leads to an order reduction to order two only.

Krogstad's method [12] for (1.1) is given by

$$
(5.16) \quad
\begin{array}{c|cccc}
0 & & & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,2} & & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,3} - \varphi_{2,3} & \varphi_{2,3} & & \\
1 & \varphi_{1,4} - 2\varphi_{2,4} & 0 & 2\varphi_{2,4} & \\
\hline
 & \varphi_1 - 3\varphi_2 + 4\varphi_3 & 2\varphi_2 - 4\varphi_3 & 2\varphi_2 - 4\varphi_3 & -\varphi_2 + 4\varphi_3
\end{array}
\quad .
$$

This method satisfies conditions 1–5 and 9 of Table 2, the weakened but sufficient condition 6 ($\psi_4(0) = 0$), but not conditions 7 and 8, which are only satisfied in a very weak form (where all arguments are evaluated for $A = 0$). In the worst case, this leads to an order reduction to order three.

Strehmel and Weiner's method [25, Example 4.5.5] can be written as

$$
(5.17) \quad
\begin{array}{c|cccc}
0 & & & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,2} & & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,3} - \frac{1}{2}\varphi_{2,3} & \frac{1}{2}\varphi_{2,3} & & \\
1 & \varphi_{1,4} - 2\varphi_{2,4} & -2\varphi_{2,4} & 4\varphi_{2,4} & \\
\hline
 & \varphi_1 - 3\varphi_2 + 4\varphi_3 & 0 & 4\varphi_2 - 8\varphi_3 & -\varphi_2 + 4\varphi_3
\end{array}
\quad .
$$

This method satisfies the conditions of Table 2 in exactly the same way as Krogstad's method. It thus converges in our situation with order three in the worst case. Strehmel and Weiner proved that the method is B-consistent of order two.

Remark. Under favorable circumstances, each of the above methods can show a higher order of convergence (generically up to order four). We will shortly discuss a typical situation when this happens. For instance, the method of Cox and Matthews satisfies condition 5 of Table 2 only in the very weak form

$$
\sum_{i=1}^{s} b_i(0) J_n \psi_{2,i}(0) = 0.
$$

According to Theorem 4.7, this may result in an order reduction down to order two. The term corresponding to condition 5 contributes to the global error via

$$
h^3 \sum_{j=0}^{n-1} e^{-(n-j-1)hA} \sum_{i=1}^{s} b_i(-hA) J_j \psi_{2,i}(-hA) f''(t_j)
$$

$$
(5.18a) \quad = h^3 \sum_{j=0}^{n-1} e^{-(n-j-1)hA} \sum_{i=1}^{s} \Big(b_i(-hA) - b_i(0) \Big) J_j \psi_{2,i}(0) f''(t_j)
$$

$$
(5.18b) \quad + h^3 \sum_{j=0}^{n-1} e^{-(n-j-1)hA} \sum_{i=1}^{s} b_i(-hA) J_j \Big(\psi_{2,i}(-hA) - \psi_{2,i}(0) \Big) f''(t_j).
$$

The first part (5.18a) has order three by Lemma 4.8. In order to improve the second term, we assume that the operators A and J_j are such that $A^{-1}J_j\widetilde{A}^\mu$ is bounded on X for some $0 \le \mu \le 1$. Then, due to

$$\left\|A^{-1}J_j\big(\psi_{2,i}(-hA) - \psi_{2,i}(0)\big)\right\|_{X\leftarrow X}$$
$$= \left\|A^{-1}J_j(h\widetilde{A})^\mu \cdot (h\widetilde{A})^{-\mu}\big(\psi_{2,i}(-hA) - \psi_{2,i}(0)\big)\right\|_{X\leftarrow X} \le Ch^\mu,$$

one gains (by applying Lemma 4.8 once more) an additional order μ in the term (5.18b). Exactly this happens in the numerical examples of section 6.

One might ask whether it is possible to modify the above methods in such a way that they have order four for semilinear parabolic problems. In fact this cannot be done without adding further stages, which is seen as follows. Assume $s = 4$, $c_2 = c_3 = 1/2$, and $c_4 = 1$. Due to the order conditions of the underlying method, we have $b_4(0) \ne 0$ and $|b_2(0)| + |b_3(0)| > 0$. Condition 5 of Table 2 immediately yields $\psi_{2,4} = 0$. Moreover, $b_3 \ne 0$ since $\psi_{2,2} \ne 0$. Hence, condition 5 can be satisfied only if $b_2 = \gamma b_3$. This leads to $\gamma\psi_{2,2} + \psi_{2,3} = 0$, which gives $a_{32} = (1 + \gamma)\frac{1}{2}\varphi_{2,3}$. This choice of a_{32} contradicts condition 8 even in the weakened form, where $b_i(-hA)$ is replaced by $b_i(0)$.

Thus we consider the case $s = 5$ and add the node $c_5 = 1/2$. In order to avoid the difficulty encountered above, we have to choose $b_2 = b_3 = 0$. This requires $b_4 b_5 \ne 0$, and therefore we have to enforce $\psi_{2,4} = \psi_{2,5} = 0$ by condition 5 for a method of order three. Thus condition 9 is satisfied automatically. Condition 8 shows that $a_{42} = \gamma a_{43}$ and $a_{52} = \gamma a_{53}$. For simplicity, we choose $\gamma = 1$. This gives $\psi_{2,2} + \psi_{2,3} = 0$, which leads to $a_{32} = \varphi_{2,3}$. Unfortunately, condition 7 cannot be satisfied in a strong form, because $\psi_{3,4} = \psi_{3,5} = 0$ contradicts $\psi_{2,4} = \psi_{2,5} = 0$. Hence we require only the weak form with $b_i(0)$ instead of $b_i(-hA)$. This yields the following fourth-order scheme:

(5.19)

$$
\begin{array}{c|ccccc}
0 & & & & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,2} & & & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,3} - \varphi_{2,3} & \varphi_{2,3} & & & \\
1 & \varphi_{1,4} - 2\varphi_{2,4} & \varphi_{2,4} & \varphi_{2,4} & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,5} - 2a_{5,2} - a_{5,4} & a_{5,2} & a_{5,2} & \frac{1}{4}\varphi_{2,5} - a_{5,2} & \\
\hline
 & \varphi_1 - 3\varphi_2 + 4\varphi_3 & 0 & 0 & -\varphi_2 + 4\varphi_3 & 4\varphi_2 - 8\varphi_3 \\
\end{array}
$$

with

$$a_{5,2} = \frac{1}{2}\varphi_{2,5} - \varphi_{3,4} + \frac{1}{4}\varphi_{2,4} - \frac{1}{2}\varphi_{3,5}.$$

6. Numerical experiments. In this section we present some numerical experiments in order to verify the sharpness of our error bounds.

As a first example we consider the semilinear parabolic problem

(6.1)
$$\frac{\partial U}{\partial t}(x,t) - \frac{\partial^2 U}{\partial x^2}(x,t) = \frac{1}{1 + U(x,t)^2} + \Phi(x,t)$$

for $x \in [0,1]$ and $t \in [0,1]$, subject to homogeneous Dirichlet boundary conditions. The source function Φ is chosen in such a way that the exact solution of the problem is $U(x,t) = x(1-x)\,\mathrm{e}^t$.
Fig. 6.1. *The errors of various explicit exponential Runge–Kutta methods of orders two to four when applied to* (6.1). *The errors are measured in the maximum norm at* $t = 1$ *and plotted as functions of the step size. For comparison, we added lines with slope two (dashed), three (dash-dotted), and four (dotted).*

We discretize this problem in space by standard finite differences with 200 grid points. Due to our theory, we expect to see order two for the two variants (5.3) and (5.4) with $c_2 = \frac{1}{2}$ of the exponential Runge method, and order three for the two variants (5.8) and (5.9) of the exponential Heun method with $c_2 = 1/3$ and $\gamma = 1.52$. Note that for this example $\|A^{-1}JA\|$ is bounded. This gives us order four for Krogstad's method and order three for the Cox and Matthews method. All these orders are confirmed by the results illustrated in Figure 6.1, where the errors are measured in the maximum norm.

Next we consider the semilinear parabolic problem

$$(6.2) \qquad \frac{\partial U}{\partial t}(x,t) - \frac{\partial^2 U}{\partial x^2}(x,t) = \int_0^1 U(x,t)\,\mathrm{d}x + \Phi(x,t)$$

for $x \in [0,1]$ and $t \in [0,1]$, subject to homogeneous Dirichlet boundary conditions. The source function Φ is again chosen such that $U(x,t) = x(1-x)\,\mathrm{e}^t$ is the exact solution.

We discretize this problem in space as in the first example, with the trapezoidal rule for the approximation of the integral. The numerical results are displayed in Figure 6.2. Again we can see order two for the two variants of the exponential Runge method and order three for the two variants of the exponential Heun method. However, since in this example only $\|A^{-1}JA^{1/2}\|$ is bounded, Krogstad's method and the Cox and Matthews method suffer from an order reduction. For Krogstad's method, we thus obtain order 3.5, while for the Cox–Matthews method we have order 2.5 only. The new exponential variant of the classical Runge–Kutta method is of full order four in this example.

In Figure 6.3 we present the errors of the 2- and 3-stage methods in the V-norm for the choice $X = L^2$ and $\alpha = 1/2$. It can be seen that method (5.3) is of order two, while method (5.4) only is of order 1.75. The order reduction for (5.4) is perfectly explained by Theorem 4.3 with $\beta = 3/4 - \varepsilon$ for arbitrary $\varepsilon > 0$, since the derivatives of f are smooth functions that do not satisfy the boundary conditions. Method (5.3), however, has full order two, since condition (4.21) holds with $\gamma = 1$ and $\mu = 1/2$. See also our detailed discussion on this topic at the end of section 4.3. By similar
FIG. 6.2. *The errors of various explicit exponential Runge–Kutta methods of orders two to four when applied to* (6.2). *The errors are measured in the maximum norm at $t = 1$ and plotted as functions of the step size. For comparison, we added lines with different slopes. In the left panel, slope two is represented by a dashed line and slope three by a dash-dotted line. In the right panel, slope* 2.5 *is represented by a dashed line, slope* 3.5 *by a dash-dotted line, and slope 4 by a dotted line.*

FIG. 6.3. *The errors of various explicit exponential Runge–Kutta methods up to order three when applied to* (6.2). *The errors are measured at $t = 1$ in a discrete V-norm for $X = L^2$ and $\alpha = 1/2$. They are plotted as a function of the step size. For comparison, we added lines with different slopes: slope* 1.75 *is represented by a dashed line, slope 2 by a dash-dotted line, and slope* 2.75 *by a dotted line.*

considerations it can be explained why the 3-stage methods show order 2.75 instead of order three in this norm.

It is beyond the scope of this paper to discuss implementation details and to compare the efficiency of exponential methods with standard implicit schemes. Such comparisons have been presented in [3, 11, 12]. Our aim here was to understand the convergence behavior of explicit methods and to present new order conditions which allow us to construct methods up to order four in a systematic way.
